Affinity chromatography is a very useful technique for "polishing", or completing the protein purification process. Beads in the chromatography column are cross-linked to ligands that bind specifically to the target protein. The protein is then removed from the column by rinsing with a solution containing free ligands.

A unified method for purification of basic proteins.

In bulk protein purification, a common first step to isolate proteins is precipitation with ammonium sulfate $(\text{NH}_4)_2\text{SO}_4$. This is performed by adding increasing amounts of ammonium sulfate and collecting the different fractions of precipitated protein. Subsequently, ammonium sulfate can be removed using dialysis.

Protein Characterization and Purification Methods

In this purification technique, proteins passed through a chromatographic column packed with a support resin to which the hydrophobic groups are covalently linked. Phenyl Sepharose, which contains a phenyl group, is commonly used in the column. Usually, the protein sample is prepared in high-salt buffer.
